| Title: How Big is a Star? |  |
| It's hard to comprehend the sheer size of objects in space, but let's give it a try! | Black background |
| If the Earth seems big, think again. 1300 Earths could fit inside Jupiter. | Earth Jupiter |
| Dwarf stars can sometimes be as small as planets. Our nearest neighbour, Proxima Centauri is just $\mathbf{2 0 0} \mathbf{0 0 0} \mathbf{~ k m}$ in diameter. <br> Our Sun is seven times bigger. | Proxima Centauri + Sun |
| Pollux, the closest orange giant star, is more than 8 x the size of the Sun. <br> Rigel, the bright blue supergiant in Orion, is $10 \times$ bigger still. | Rigel |
| Red supergiant Betelgeuse is even bigger and it's on the verge of going supernova. <br> \#ExplosiveStuff | Betelgeuse |
| Red hypergiant VY Canis Majoris is $\mathbf{2}$ billion kilometres across! <br> More than 1400 x larger than the Sun. Mind boggling! | VY Canis Majoris <br> Hyperfast travel back to Earth |
